Metacognitive and Nonmetacognitive Influence of Affect in Judgment

Tamar Avnet, Yeshiva University
Michel Tuan Pham, Columbia University

Multiple experiments using a new procedure to manipulate the perceived diagnosticity of feelings suggest that the influence of feelings on judgment may involve two separate mechanisms: one, consistent with the idea of affect-as-information, involves a metacognitive assessment of whether one’s feelings should be trusted in the judgment; the other involves a more mindless use of feelings without much consideration for their information value. The former mechanism requires cognitive resources; the later takes place when resources are limited.

the technical” (Sørensen 2006, p. 46). Herein, we focus on two aspects of domestication–objectification which is concerned with the spatial aspects and incorporation which deals with the temporal aspects of domestication (Silverstone et al. 2006). An overarching theme that emerges from our data is “control,” related to the space and time needed to create family identity and cohesion.

With regard to objectification, our informants deliberately and strategically locate technology in the home to facilitate family togetherness. In many homes, computers, webcams, and other information and communication technologies are placed in the public space of the living area and often serving as a center for family togetherness (e.g., a family movie or game night). In some instances, placement of technology is an artifact of the lack of space in “old” on-post housing units. However, in “new” on-post housing units with extra space, families make conscious decisions to locate ICTs and orchestrate space around ICTs. Consistent with other work (e.g., Mick and Fournier 1998), our informants acknowledge that ICTs have the ability to disrupt family identity if they are not carefully monitored and managed, a factor which partially drives the integration of ICTs into central spaces.

Our findings also document incorporation of technology into daily life. ICTs induce changes in the management of temporal patterns in domestic life. Family unity is particularly relevant when the family’s soldier is deployed, and ICTs offer a metaphorical bridge between the physical space of home and the front, and family’s “control.” Through ICTs, informants make their husbands “present” for the birth of babies, birthday parties, and other family events. ICTs are an important tool for building not only the immediate Army family (see also Kosova 2007), but also constitute a social, bonding space for extended kin relationships. Family photo websites, emails and other computer-mediated communication constitute an important relationship maintenance infrastructure not only for the immediate family but also for neighbors, other military wives, and Army support staff who, on occasion, or with some regularity, become part of the family unit. Despite the positive aspects of ICTs in sustaining and building family, informants are mindful of the “evils of technology” that have the potential to degrade the family unit. Army mothers monitor not only the content of, but also the time allocated to computers, XBox, television, and other technologies. Many set a timer, others keep written records. A key concern is having their children “get lost” in the technology.

Consistent with domestication research, we find that meanings of technology in the home are neither positive nor negative, but rather are negotiated by the family (Bakardjieva 2006). Indeed, the family, its rituals, scripts and dynamics, as well as values and goals impact not only the acquisition of technology, but also the nature of the objectification and incorporation of ICTs within the household.

The Role of Power In Consumer Behavior: New Perspectives and Insights

Derek D. Rucker, Northwestern University, USA

SESSION OVERVIEW

Power, defined as the capacity to control one’s own and others’ resources and outcomes (Hunt and Nevin 1974; Keltner et al., Gruenfeld and Anderson 2003), is perhaps one of the most omnipresent forces in consumers’ lives. Throughout the day consumers likely have experiences of feeling both powerful and powerless. For example, meeting with one’s boss might evoke feeling powerless, but interviewing a potential employee may evoke feeling powerful. What is the role of power in consumer behavior? Does feeling powerful lead to an increased willingness to pay a premium price for products, or might it have the opposite effect? Do momentary states of power affect consumers’ response to persuasive messages? Does power activate a single goal, or could there be different goals associated with power? This symposium unites under a common theme of providing understanding of the role of power in consumer behavior.

The first paper by Rucker and Galinsky examines how states of power affect consumers’ spending behavior. Recognizing powerlessness is an aversive state, these authors propose that powerlessness may serve a previously unexplored role of motivating consumers to restore power. Because status is one source of power, they suggest consumers would be willing to pay a premium for status-related products in an effort to restore power. In three experiments, these authors find evidence that placing consumers in a state of low power provokes a greater willingness to pay for products associated with status, but not with products unassociated with status. This work provides insights into the role of power in consumer behavior, and provides evidence for a new compensatory process evoked by power.

The second paper by Briñol and colleagues explores how power affects consumers’ attitudes towards a persuasive message and whether this is dependent upon when power is induced—before or after a persuasive communication. Briñol and colleagues suggest power validates whatever mental constructs are accessible to consumers. They hypothesize that before persuasion power produces a general sense of confidence in one’s views that leads consumers to process subsequent information less carefully. However, after persuasion, they suggest power enhances consumers’ reliance on their thoughts. These authors provide evidence for both of these effects and demonstrate how power can differentially affect persuasion depending on whether it is induced before or after persuasion. This stream of research provides an important insight into how power affects consumers’ attitudes, intentions, and information processing.

The final paper by Torelli and Shavitt enhances our understanding of power by distinguishing between notions of power as status and power for the benefit of others. In three experiments, the authors find that consumers’ information processing efforts are not dependent solely on the activation of power, but the particular notion of power held by consumers. Specifically, those who are relatively high in vertical-individualism engage in more stereotyping, presumably to preserve their power identity, whereas those who are relatively high in horizontal-collectivism engage in more individuating, presumably in order to form careful impressions that could be helpful to others.

This session discusses a topic that has received little prior research attention in the consumer behavior literature, but has amazing potential to both inform consumer research and stimulate future research efforts. We anticipate this session will attract not only those interested in attitudes and information processing, but those interested in studying the topic of power that is beginning to emerge in consumer research. Joseph Priester, an expert in information processing and persuasion, will weave together the implications of the three streams of research and paint a picture of the future research questions for research in power and consumer behavior.

EXTENDED ABSTRACTS

“The Role of Power in Consumer Spending”

Derek D. Rucker, Northwestern University

Adam D. Galinsky, Northwestern University

How does power affect consumers’ spending habits? Past research suggests that power tends to be associated with action (Galinsky, Gruenfeld, and Magee 2003) such that states of feeling powerful prompt greater action and greater risk-taking (Anderson and Galinsky 2006). Thus, one potential role for power in consumer spending is that power would lead to greater spending (i.e., paying whatever it takes to acquire an item). Indeed, such a prediction might also be hypothesized based on a general association of power with resources (e.g., Keltner et al. 2003), indicating those feeling powerful may perceive themselves as having more resources to allocate to obtaining consumer products.

We propose, however, that power may play a very different role in consumer spending. Several research streams suggest that power is an aversive state such that people often have a more negative response when in a state of low power (Keltner et al. 2003). As an aversive state, we hypothesize that consumers are likely to want to reduce feelings of powerlessness. Past research suggests that status is one form of power (e.g., French and Raven 1959). Furthermore, research suggests that consumer products serve the function of communicating information about one’s status (e.g., Belk, Bahn, and Mayer 1982). For instance, Belk and colleagues (1982) discuss the notion that consumer products may signal or convey one’s status. Belk and colleagues note, “It may be that concern with demonstrating status to others comes to dominate other consumption message interests sometime after the eighth grade and that this concern then continues.”

Power and Consumer Spending: The Compensatory Hypothesis. Given low power is often an aversive psychological state, we hypothesize that consumers may seek to compensate for feelings of powerlessness by obtaining or signaling status. Further, we suggest acquiring consumer products and goods represent one means by which consumers may attempt to restore their lost power. Status has often been viewed as one basis of power (French and Raven 1959) and indeed, status often determines the resources or control one is given or able to allocate within a group (Kemper 1991). Consequently, we hypothesize that, when placed in a psychological state of low power, consumers may be attracted to and seek to acquire products that are naturally associated with status (e.g., business attire, executive pens). By acquiring products associated with status, consumers may compensate for their feelings of powerlessness. If true, we hypothesize that consumers’ willingness to spend money on products associated with status should increase when they are in a state of low power. This increased expenditure should stem from a greater perceived psychological benefit of the product in addressing their needs.
In experiment 1, we examined the extent to which power affects participants’ willingness to pay for products that have an association to status. Power was induced by instructing participants to write about a time they either had low or high power, a manipulation clearly established to affect participants’ state of power (Galinsky et al., 2003). In addition, a control group was included where participants simply described their last trip to the grocery store. Then, as part of an ostensibly unrelated study, participants were asked to indicate their willingness to pay for various consumer products. Results revealed that low-power participants compared to high-power or control participants, indicated a greater willingness to pay for items associated with status (e.g., Italian suit, briefcase, silk tie) but there were no differences in items unassociated with status (e.g., sofa, t-shirt, minivan).

In experiment 2, we examined whether the effects hold for the same consumer product by simply framing the product as being associated with or unassociated with status. Specifically, after receiving the power manipulation used in experiment 1, all participants were asked to indicate their willingness to pay for a portrait of their university. However, the product was either described as common and conveying no status or special association or as rare and conveying prestige and status. Replicating experiment 1, we found participants placed in a state of low power, compared to high power and control conditions, were significantly higher in their willingness to pay for the same item, but only when the product was framed as having status.

In a third experiment, we found that consumers’ increased willingness to pay for items associated with status is due to the perception that obtaining those items will provide a sense of power to them. In addition, throughout the experiments we included items to assess competing interpretations of the data (e.g., mood), and find little evidence for alternative accounts.

Conclusion and Contributions. The present research provides evidence for a new mechanism by which power can affect behavior. We believe the present findings offer advances in understanding the role of power in consumer behavior and, more generally, the state of power. Theoretical and practical implications of this work in understanding power in consumer behavior are discussed.

“The Validating Effects of Power: Implications for Consumer Persuasion”

Pablo Briñol, Universidad Autonoma de Madrid
Richard E. Petty, Ohio State University
Carmen Valle, Universidad San Pablo Ceu

Building on previous research demonstrating that power is associated with approach tendencies (Galinsky, et al. 2003), we argue that greater levels of power might be associated with increased confidence in whatever mental constructs are accessible at the time. We provide an initial experiment to demonstrate the existence of a power-confidence link. We subsequently hypothesized power, via its relationship with confidence, would have divergent effects depending on whether power was induced before or after persuasion because of the mental constructs likely activated.

First, we hypothesized before information processing consumers’ must decide how carefully to process information. As a consequence, we anticipated that inducing power before information processing would affect consumers’ decision of how carefully to process subsequent information. Feeling powerful, compared to powerless, should induce confidence in one’s position, and past research has shown that states of confidence lead people to process subsequent information less thoroughly (e.g., Tiedens and Linton 2001). If consumers’ process information less carefully when they feel powerful, this should lead to a poorer discrimination between weak and strong arguments (Petty and Cacioppo 1986) due to differences in information processing.

Second, we hypothesized that after information processing consumers’ no longer need to decide whether to process but whether to rely upon or trust their own thoughts in response to the message. As a result, we hypothesized that feeling powerful, compared to powerless, should induce greater confidence in one’s thoughts, and past research has shown that people are more likely to rely upon their thoughts when those thoughts are held with confidence (Briñol, Petty, and Tormala 2004). Importantly, if consumers’ rely upon their thoughts more when they are feeling powerful, this should lead to a great distinction between weak and strong arguments (Briñol et al., 2004) due to differential thought reliance.

Experiment 1: Linking Power and Confidence. Participants were randomly assigned to the high-power or low-power conditions. Power was manipulated by asking participants to play the role of a supervisor or an employee in a work simulation game (Galinsky, et al. 2003). Following this induction, participants rated their confidence and feelings of power. We predicted and found that participants in the high-power condition felt more confident and powerful that low-power individuals. This supported our hypothesized link between power and confidence.

Experiment 2: Manipulating Power Before Information Processing. Power was manipulated between participants using the same manipulation as in experiment 1. After completing the power induction task, as part of a supposedly unrelated study, participants were asked to evaluate a printed advertisement promoting a new cell phone containing either strong or weak arguments. Argument quality was varied in this study to assess consumers’ information processing activity. Specifically, the greater information processing, the more (less) favorable consumers should be when receiving strong (weak) arguments. Finally, all participants reported their attitudes toward the product. If power does influence participants’ confidence in their views when deciding whether to process a message, participants who are powerful should show less information processing than participants who are less powerful. Consistent with predictions, we found that the effect of argument quality on consumer attitudes was smaller when consumers had been induced into a state of high, as opposed to low, power.

Experiment 3: Manipulating Power After Information Processing. Participants were first exposed to a printed advertisement promoting a new cell phone containing either strong or weak arguments. Prior to providing their attitudes, however, participants were told the experimenter need to make copies of the dependent measures and thus they should work on a new experimental task. Power was then experimentally induced using the same role-playing technique described in prior experiments. After completing the power manipulation, the experimenter returned with the final measures and participants reported their attitudes toward the product. If, when induced after information processing, power does influence the confidence with which people hold their thoughts, we would expect high power to increase the argument quality effects, that is, more persuasion with the strong than the weak ad. In line with this hypothesis, we found that the effect of argument quality on consumers’ attitudes was greater when consumers had high rather than low confidence in their cognitive responses. Thus, with relatively high confidence, consumers relied on their thoughts in forming attitudes, but with relatively low confidence, consumers did not use their thoughts to judge the product (producing a lower attitude-thought correspondence).
**Discussion.** In the present work we not only demonstrate a link between power and confidence, but demonstrated that power could have different effects on persuasion depending on when power is induced. Specifically, when induced prior to information processing power affected how carefully consumers processed a message. However, when induced after information processing power affected the confidence consumers placed in their thoughts. As a result, a strong message was more persuasive for low power participants when power was induced before information processing, but a strong message was more persuasive for high power participants when power was induced after information processing.

Taken together, these findings are important because they identify new roles for power in the persuasion process.

*pCulture and Mental Representations of Power Goals: Consequences for Information Processing*

Carlos J. Torelli, University of Minnesota
Sharon Shavitt, University of Illinois

This research investigates the consequences of activating different types of power goals on consumer information-processing strategies. People’s culturally-related values and beliefs are used to predict the types of power-goals activated when power is made salient. We examine the role of cultural orientation in consumer contexts that make power salient, the types of power goals that individuals bring to mind in those contexts, and the information processing consequences of activating those goals.

In the present research, we focus here on 2 types of power goals: 1) personalized power (i.e., self-focused) goals of seeking status in order to gain recognition and admiration from others and, 2) socialized power (i.e., other-focused) goals of helping and having a positive effect on others (McClelland 1973). In previous studies, we have found that whether people pursue personalized vs. socialized power goals is predicted by their culturally-related values and beliefs. We separate different cultural orientations using the vertical-horizontal distinction nested within the broader individualism-collectivism classification (Triandis and Gelfand 1998). We find that individuals high in vertical-individualism (VI) associate power with personalized goals of seeking status, whereas individuals high in horizontal-collectivism (HC) associate power with prosocial goals of helping others. We use the goals that high-VI and -HC individuals associate with power to better predict how they process information when power is salient.

Previous research indicates that powerholders frequently use stereotypes for their judgments. Stereotyping protects relevant beliefs about who should have control and protects existing power identities (e.g., Fiske 2001). However, powerholders who focus on their effects on the well-being of others often attend to individuating information (Goodwin et al. 2000). We propose that the way in which people process information when power is salient will be impacted by the culturally-nurtured associations they have established with power. Powerholders relatively high in VI, who associate power with personalized goals of seeking status, would engage in more stereotyping. In contrast, powerholders relatively high in HC, who associate power with prosocial goals of helping others, would attend more to individuating information.

Results from 3 experiments support the notion that, when power is salient, individuals relatively high in VI stereotype more. They attend more to and remember better information that is congruent with their prior expectations about target products, whereas such effects are absent among low-VI participants. In contrast, individuals high (vs. low) in HC attend more to and remember better the information incongruent with their prior expectations about target products. In all experiments, cultural orientation was measured using Triandis and Gelfand’s (1998) scale.

In experiment 1, we examined the effects of personalized (status-enhancing) versus socialized (helping-others) power cues embedded in product messages on the way participants processed the messages. Participants read initial information about either a status enhancing (i.e., facilitates achieving high-status) or a nurturing product (i.e., that impacts others positively). Along with this initial information, participants read additional information both congruent and incongruent with the initial description of the product. After a filler task, they received a surprise recognition task for the product information. As expected, people high in VI stereotyped more after reading information about the status-enhancing (and not about the nurturing) product. That is, they remembered better the congruent (relative to incongruent) information, whereas such effects were absent among participants low in VI. We argue that status-seeking goals activated by the product description led high-VI individuals to stereotype more. In contrast, individuals high (vs. low) in HC processed in a more individuating manner after reading information about the nurturing product (but not the status-enhancing product). That is, high-HC individuals had higher recognition for incongruent information. We argue that prosocial goals activated by the product description led high-HC participants to individuate more.

In experiment 2, participants recalled events associated with exercises of either personalized or socialized power. Subsequently, they received messages about a known brand (McDonald’s). We measured attention and memory for attributes congruent and incongruent with the McDonald’s stereotype of unhealthiness and convenience. Results showed that individuals high (vs. low) in HC, after being primed with socialized power, were more likely to emphasize the incongruent attributes when writing a product review about McDonald’s and had higher recognition for these attributes. We argue that helping-others goals activated by high HC participants after being primed with socialized (and not with personalized) power led them to individuate more. In contrast, participants high (vs. low) in VI stereotyped more after being primed with personalized power. They emphasized more congruent (relative to incongruent) attributes when writing a product review about McDonald’s. In addition, they were the only ones who showed an advantage in recognition of information congruent with McDonald’s stereotype.

Finally, experiment 3 followed a similar procedure to experiment 2, but used alternative power primes. The same pattern of results from the previous experiment emerged using new power primes. Furthermore, the results were contrasted with a control (no power) condition in which the stereotyping and individuating effects were absent. In summary, this research addresses the information processing strategies used by individuals with different cultural orientations in consumer settings that make power salient. It highlights the important role of culturally-nurtured associations with power for determining the effects of power primes on basic cognitive processes. Ultimately, a focus on the distinction between personalized and socialized power goals can enhance our understanding of the role of power in consumer behavior. We discuss consequences for consumers’ judgments, preferences, and influence attempts.
